Lab 4: VibeCoding

ChatGPT conversation history — reaction-time-tester assignment

Note: This is a compiled transcript of the Lab 4 discussion available in this chat context. Some earlier turns were marked as skipped, so this PDF cannot reproduce messages that are not available here. It includes the assignment details and the guidance exchanged about setup, fixing, recording, deliverables, and GitHub submission.

User

Asked what the term is for pushing a document/code into Git and whether a Git repository is needed.

User

Shared the assigned repository: https://github.com/SETAPESU26/43_reaction-time-tester and asked to fix errors.

User

Shared Lab 4: VibeCoding instructions. Objective: use an AI assistant to debug and extend a partially working Pygame reaction-time tester, clone/fork the assigned repository, record 10 seconds before and after changes, implement the README features, and push to a personal account. Do not raise a PR to SETAPESU26.

User

Shared the README requirements: (1) measure reaction time from the green cue and flag grey-screen false starts; (2) show a results screen with every reaction time and average; (3) allow replay with Easy/Medium/Hard difficulty or exit; (4) add sound effects for go, false start, and session end.

Assistant

Explained that the game should be run from the cloned project folder and that the Mac terminal uses python3 / a virtual environment. The initial 'code .' command failed because the 'code' shell command was not installed or configured.

User

Shared a screenshot showing the cloned repository in VS Code, with game/, main.py, README.md, and requirements.txt.

Assistant

Recommended installing dependencies inside the project virtual environment and running the game from the repository directory, not from the parent Lab4_VibeCoding directory.

User

Shared an installation error: Pygame failed to build in the current Python environment.

Assistant

Advised using a compatible Python version/environment and the project's virtual environment rather than installing into Homebrew's externally managed Python. Later, the user successfully ran the game using Pygame 2.6.1 with Python 3.12.14.

User

Asked when to record and what to capture for the final deliverables.

Assistant

Explained that the BEFORE video must be recorded before code changes and should show the original bug/broken behavior; the AFTER video should show the fixed game and new features. The submission includes both videos, updated code, and chat history.

User

Said the first BEFORE recording was completed and asked what to do next.

Assistant

Guided the user to inspect the project, run the original game, and use the AI coding Agent to fix the issues and implement the README features.

User

Shared a screenshot of the VS Code Agent permission/evaluation panel.

Assistant

Explained that the Agent was evaluating the project and advised waiting briefly, allowing the workspace analysis if prompted, and sending a concise instruction to proceed if it remained stuck.

User

Shared a screenshot showing the Agent edited round.py, game_engine.py, and main.py, and the terminal ran the game successfully.

Assistant

Recommended accepting the changes with Keep, then asking the Agent to verify the four README tasks. It advised not recording the AFTER video until the features were tested.

User

Asked whether to press Keep.

Assistant

Confirmed to press Keep to accept the Agent's proposed edits, then run the updated game and test it before recording.

User

Shared the Agent's implementation/validation summary.

Assistant

Summarized the reported changes: corrected timing from green cue, false-start handling, results screen, replay/difficulty, synthesized sound cues, and main loop notification after display. The Agent reported compile checks and smoke checks passed, but the game still needed hands-on testing.

User

Confirmed the updated game ran and that an AFTER recording was made.

Assistant

Moved to final GitHub and submission steps: check git status and remote, create a personal repository if needed, push only to the personal repository, and organize Lab-4 deliverables.

User

Asked whether the AFTER recording was correct.

Assistant

Advised that gameplay and some updated behavior were visible, but the clip was longer than the required 10 seconds and did not clearly show all features. Suggested keeping it as backup and recording a concise clip.

User

Asked whether another recording was fine.

Assistant

Recommended a clear 10-second clip featuring a final round, results screen, average, and replay menu if possible; separately verify all features.

User

Said they forgot to take the BEFORE video and asked to check the pasted document.

Assistant

Referred to the assignment requirement for a 10-second BEFORE video and suggested either recovering the original committed files temporarily to reproduce the bug and record it, or submitting without the missing video while acknowledging the incomplete requirement.

User

Shared git status showing uncommitted modifications in game_engine.py, round.py, and main.py, plus untracked .venv and a nested clone directory.

Assistant

Explained that uncommitted changes could be backed up, original files restored temporarily with git restore, the original bug recorded, and the updated code copied back from the backup. Warned not to use git reset --hard.

User

Asked to complete the final deliverables.

Assistant

Provided a checklist and instructions to restore final code, create Lab-4/updated-code, copy main.py, requirements.txt, game_engine.py, and round.py, place before/after videos and chat-history PDF in Lab-4, then verify the personal GitHub remote and push.

User

Shared terminal screenshot showing cp failed because commands were run from Documents rather than inside the repository.

Assistant

Identified the wrong working directory and instructed the user to cd into ~/Documents/Lab4_VibeCoding/43_reaction-time-tester, create Lab-4/updated-code/game, and copy the four code files.

User

Shared terminal screenshot showing successful copies and find output listing all four updated-code files.

Assistant

Confirmed the code files were copied successfully and instructed the user to add the two videos and chat-history PDF, then run find Lab-4 -type f and git remote -v before pushing.

User

Asked for a PDF of this GPT history.
